

Goals as Reward-Generating Programs Domain Specific Language

October 26, 2022

1 DSL Grammar Definitions

A game is defined by a name, and is expected to be valid in a particular domain, also referenced by a name. A game is defined by four elements, two of them mandatory, and two optional. The mandatory ones are the $\langle constraints \rangle$ section, which defines gameplay preferences, and the $\langle scoring \rangle$ section, which defines how gameplay preferences are counted to arrive at a score for the player in the game. The optional ones are the $\langle setup \rangle$ section, which defines how the environment must be prepared before gameplay can begin, and the $\langle terminal \rangle$ conditions, which specify when and how the game ends.

```
 $\langle game \rangle ::=$  (define (game  $\langle name \rangle$ )  
  (:domain  $\langle name \rangle$ )  
  (:setup  $\langle setup \rangle$ )  
  (:constraints  $\langle constraints \rangle$ )  
  (:terminal  $\langle terminal \rangle$ )  
  (:scoring  $\langle scoring \rangle$ )  
  )
```

$\langle name \rangle ::=$ /[A-z]+(_[A-z0-9]+)*/ # a letter, optionally followed by letters, numbers, and underscores

We will now proceed to introduce and define the syntax for each of these sections, followed by the non-grammar elements of our domain: predicates, functions, and types. Finally, we provide a mapping between some aspects of our gameplay preference specification and linear temporal logic (LTL) operators.

1.1 Setup

The setup section specifies how the environment must be transformed from its deterministic initial conditions to a state gameplay can begin at. Currently, a particular environment room always appears in the same initial conditions, in terms of which objects exist and where they are placed. Participants in our experiment could, but did not have to, specify how the room must be setup so that their game could be played.

The initial $\langle setup \rangle$ element can expand to conjunctions, disjunctions, negations, or quantifications of itself, and then to the $\langle setup-statement \rangle$ rule. $\langle setup-statement \rangle$ elements specify two different types of setup conditions: either those that must be conserved through gameplay ('game-conserved'), or those that are optional through gameplay ('game-optional'). These different conditions arise as some setup elements must be maintain through gameplay (for example, a participant specified to place a bin on the bed to throw balls into, it shouldn't move unless specified otherwise), while other setup elements can or must change (if a participant specified to set the balls on the desk to throw them, an agent will have to pick them up (and off the desk) in order to throw them).

Inside the $\langle setup-statement \rangle$ tags we find $\langle setup-predicate \rangle$ elements, which can again resolve into logical conditions and quantifications of other $\langle setup-predicate \rangle$ elements, but also to function comparisons ($\langle f-comp \rangle$) and predicates ($\langle predicate \rangle$). Function comparisons usually consist of a comparison operator and two arguments, which can either be the evaluation of a function or a number. The one exception is the case where the comparison operator is the equality operator (=), in which case any number of arguments can be provided. Finally, the $\langle predicate \rangle$ element expands to a predicate acting on one or more objects or variables. We assume the list of predicate existing in a domain will be provided to any models as part of their inputs rather than hard-coded into the grammar. For a full list of the predicates we found ourselves using so far, see subsection 2.1 (Predicates).

```
 $\langle setup \rangle ::=$  (and  $\langle setup \rangle$   $\langle setup \rangle^+$ ) # A setup can be expanded to a conjunction, a disjunction, a quantification, or a setup  
  statement (see below).  
  | (or  $\langle setup \rangle$   $\langle setup \rangle^+$ )  
  | (not  $\langle setup \rangle$ )  
  | (exists ( $\langle typed\ list(variable) \rangle$ )  $\langle setup \rangle$ )  
  | (forall ( $\langle typed\ list(variable) \rangle$ )  $\langle setup \rangle$ )  
  |  $\langle setup-statement \rangle$ 
```

$\langle \text{setup-statement} \rangle ::= \#$ A setup statement specifies that a predicate is either optional during gameplay or must be preserved during gameplay.

- | $(\text{game-conserved } \langle \text{super-predicate} \rangle)$
- | $(\text{game-optional } \langle \text{super-predicate} \rangle)$

$\langle \text{super-predicate} \rangle ::= \#$ A super-predicate is a conjunction, disjunction, negation, or quantification over another super-predicate. It can also be directly a function comparison or a predicate.

- | $(\text{and } \langle \text{super-predicate} \rangle^+)$
- | $(\text{or } \langle \text{super-predicate} \rangle^+)$
- | $(\text{not } \langle \text{super-predicate} \rangle)$
- | $(\text{exists } (\langle \text{typed list(variable)} \rangle) \langle \text{super-predicate} \rangle)$
- | $(\text{forall } (\langle \text{typed list(variable)} \rangle) \langle \text{super-predicate} \rangle)$
- | $\langle \text{f-comp} \rangle$
- | $\langle \text{predicate} \rangle$

$\langle \text{f-comp} \rangle ::= \#$ A function comparison: either comparing two function evaluations, or checking that two ore more functions evaluate to the same result.

- | $(\langle \text{comp-op} \rangle \langle \text{function-eval-or-number} \rangle \langle \text{function-eval-or-number} \rangle)$
- | $(= \langle \text{function-eval-or-number} \rangle^+)$

$\langle \text{comp-op} \rangle ::= \langle \mid \langle = \mid = \mid \rangle \mid \rangle = \#$ Any of the comparison operators.

$\langle \text{function-eval-or-number} \rangle ::= \langle \text{function-eval} \rangle \mid \langle \text{number} \rangle$

$\langle \text{function-eval} \rangle ::= (\langle \text{name} \rangle \langle \text{function-term} \rangle^+) \#$ An evaluation of a function on any number of arguments.

$\langle \text{function-term} \rangle ::= \langle \text{name} \rangle \mid \langle \text{variable} \rangle \mid \langle \text{number} \rangle$

$\langle \text{variable-list} \rangle ::= (\langle \text{variable-type-def} \rangle^+) \#$ One or more variables definitions, enclosed by parentheses.

$\langle \text{variable-type-def} \rangle ::= \langle \text{variable} \rangle^+ - \langle \text{type-def} \rangle \#$ Each variable is defined by a variable (see next) and a type (see after).

$\langle \text{variable} \rangle ::= /\backslash?[a-z][a-z0-9]^*/ \#$ a question mark followed by a letter, optionally followed by additional letters or numbers.

$\langle \text{type-def} \rangle ::= \langle \text{name} \rangle \mid \langle \text{either-types} \rangle \#$ A variable type can either be a single name, or a list of type names, as specified by the next rule:

$\langle \text{either-types} \rangle ::= (\text{either } \langle \text{name} \rangle^+)$

$\langle \text{predicate} \rangle ::= (\langle \text{name} \rangle \langle \text{predicate-term} \rangle^*)$

$\langle \text{predicate-term} \rangle ::= \langle \text{name} \rangle \mid \langle \text{variable} \rangle$

1.2 Gameplay Preferences

The gameplay preferences specify the core of a game's semantics, capturing how a game should be played by specifying temporal constraints over predicates. The name for the overall element, $\langle \text{constraints} \rangle$, is inherited from the PDDL element with the same name.

The $\langle \text{constraints} \rangle$ elements expands into one or more preference definitions, which are defined using the $\langle \text{pref-def} \rangle$ element. A $\langle \text{pref-def} \rangle$ either expands to a single preference ($\langle \text{preference} \rangle$), or to a $\langle \text{pref-forall} \rangle$ element, which specifies variants of the same preference for different objects, which can be treated differently in the scoring section. A $\langle \text{preference} \rangle$ is defined by a name and a $\langle \text{preference-quantifier} \rangle$, which expands to an optional quantification (exists, forall, or neither), inside of which we find the $\langle \text{preference-body} \rangle$.

A $\langle \text{preference-body} \rangle$ expands into one of two options: The first is a set of conditions that should be true at the end of gameplay, using the $\langle \text{at-end} \rangle$ operator. Inside an $\langle \text{at-end} \rangle$ we find a $\langle \text{pref-predicate} \rangle$, which like the $\langle \text{setup-predicate} \rangle$ term, can expand to logical operations over predicates, quantifications over predicates, a function comparison, or a predicate.

The second option is specified using the $\langle \text{then} \rangle$ syntax, which defines a series of temporal conditions that should hold over a sequence of states. Under a $\langle \text{then} \rangle$ operator, we find two or more sequence functions ($\langle \text{seq-func} \rangle$), which define the specific

conditions that must hold and how many states we expect them to hold for. We assume that there are no unaccounted states between the states accounted for by the different operators – in other words, the $\langle then \rangle$ operators expects to find a sequence of contiguous states that satisfy the different sequence functions. The operators under a $\langle then \rangle$ operator map onto linear temporal logic (LTL) operators, see ?? (??) for the mapping and examples.

The $\langle once \rangle$ operator specifies a predicate that must hold for a single world state. If a $\langle once \rangle$ operators appears as the first operator of a $\langle then \rangle$ definition, and a sequence of states S_a, S_{a+1}, \dots, S_b satisfy the $\langle then \rangle$ operator, it could be the case that the predicate is satisfied before this sequence of states (e.g. by S_{a-1}, S_{a-2} , and so forth). However, only the final such state, S_a , is required for the preference to be satisfied. The same could be true at the end of the sequence: if a $\langle then \rangle$ operator ends with a $\langle once \rangle$ term, there could be other states after the final state (S_{b+1}, S_{b+2} , etc.) that satisfy the predicate in the $\langle once \rangle$ operator, but only one is required. The $\langle once\text{-}measure \rangle$ operator is a slight variation of the $\langle once \rangle$ operator, which in addition to a predicate, takes in a function evaluation, and measures the value of the function evaluated at the state that satisfies the preference. This function value can then be used in the scoring definition, see subsection 1.4 (Scoring).

A second type of operator that exists is the $\langle hold \rangle$ operator. It specifies that a predicate must hold true in every state between the one in which the previous operator is satisfied, and until one in which the next operator is satisfied. If a $\langle hold \rangle$ operator appears at the beginning or an end of a $\langle then \rangle$ sequence, it can be satisfied by a single state, Otherwise, it must be satisfied until the next operator is satisfied. For example, in the minimal definition below:

```
(then
  (once (pred_a))
  (hold (pred_b))
  (once (pred_c))
)
```

To find a sequence of states S_a, S_{a+1}, \dots, S_b that satisfy this $\langle then \rangle$ operator, the following conditions must hold true: (1) pred_a is true at state S_a , (2) pred_b is true in all states $S_{a+1}, S_{a+2}, \dots, S_{b-2}, S_{b-1}$, and (3) pred_c is true in state S_b . There is no minimal number of states that the hold predicate must hold for.

The last operator is $\langle hold\text{-}while \rangle$, which offers a variation of the $\langle hold \rangle$ operator. A $\langle hold\text{-}while \rangle$ receives at least two predicates. The first acts the same as predicate in a $\langle hold \rangle$ operator. The second (and third, and any subsequent ones), must hold true for at least state while the first predicate holds, and must occur in the order specified. In the example above, if we substitute $(\text{hold } (\text{pred_b}))$ for $(\text{hold-while } (\text{pred_b}) (\text{pred_d}) (\text{pred_e}))$, we now expect that in addition to pred_b being true in all states $S_{a+1}, S_{a+2}, \dots, S_{b-2}, S_{b-1}$, that there is some state $S_d, d \in [a + 1, b - 1]$ where pred_d holds, and another state, $S_e, e \in [d + 1, b - 1]$ where pred_e holds.

$\langle constraints \rangle ::= \langle pref\text{-}def \rangle \mid (\text{and } \langle pref\text{-}def \rangle^+) \#$ One or more preferences.

$\langle pref\text{-}def \rangle ::= \langle pref\text{-}forall \rangle \mid \langle preference \rangle \#$ A preference definitions expands to either a forall quantification (see below) or to a preference.

$\langle pref\text{-}forall \rangle ::= (\text{forall } \langle variable\text{-}list \rangle \langle preference \rangle) \#$ this syntax is used to specify variants of the same preference for different objects, which differ in their scoring. These are specified using the $\langle pref\text{-}name\text{-}and\text{-}types \rangle$ syntax element's optional types, see scoring below.

$\langle preference \rangle ::= (\text{preference } \langle name \rangle \langle preference\text{-}quantifier \rangle) \#$ A preference is defined by a name and a quantifier that includes the preference body.

$\langle preference\text{-}quantifier \rangle ::= \#$ A preference can quantify existentially or universally over one or more variables, or none.
 $\mid (\text{exists } (\langle variable\text{-}list \rangle) \langle preference\text{-}body \rangle)$
 $\mid (\text{forall } (\langle variable\text{-}list \rangle) \langle preference\text{-}body \rangle)$
 $\mid \langle preference\text{-}body \rangle$

$\langle preference\text{-}body \rangle ::= \langle then \rangle \mid \langle at\text{-}end \rangle$

$\langle at\text{-}end \rangle ::= (\text{at-end } \langle super\text{-}predicate \rangle) \#$ Specifies a predicate that should hold in the terminal state.

$\langle then \rangle ::= (\text{then } \langle seq\text{-}func \rangle \langle seq\text{-}func \rangle^+) \#$ Specifies a series of conditions that should hold over a sequence of states – see below for the specific operators ($\langle seq\text{-}func \rangle$ s), and Section 2 for translation of these definitions to linear temporal logic (LTL).

$\langle seq\text{-}func \rangle ::= \langle once \rangle \mid \langle once\text{-}measure \rangle \mid \langle hold \rangle \mid \langle hold\text{-}while \rangle \#$ Four of these temporal sequence functions currently exist:

$\langle \text{once} \rangle ::= (\text{once } \langle \text{super-predicate} \rangle) \#$ The predicate specified must hold for a single world state.

$\langle \text{once-measure} \rangle ::= (\text{once } \langle \text{super-predicate} \rangle \langle \text{function-eval} \rangle) \#$ The predicate specified must hold for a single world state, and record the value of the function evaluation, to be used in scoring.

$\langle \text{hold} \rangle ::= (\text{hold } \langle \text{super-predicate} \rangle) \#$ The predicate specified must hold for every state between the previous temporal operator and the next one.

$\langle \text{hold-while} \rangle ::= (\text{hold-while } \langle \text{super-predicate} \rangle \langle \text{super-predicate} \rangle^+) \#$ The first predicate specified must hold for every state between the previous temporal operator and the next one. While it does, at least one state must satisfy each of the predicates specified in the second argument onward

For the full specification of the $\langle \text{super-predicate} \rangle$ element, see subsection 1.1 (Setup) above.

1.3 Terminal Conditions

Specifying explicit terminal conditions is optional, and while some of our participants chose to do so, many did not. Conditions explicitly specified in this section terminate the game. If none are specified, a game is assumed to terminate whenever the player chooses to end the game.

The terminal conditions expand from the $\langle \text{terminal} \rangle$ element, which can expand to logical conditions on nested $\langle \text{terminal} \rangle$ elements, or to a terminal comparison. The terminal comparison ($\langle \text{terminal-comp} \rangle$) compares two scoring expressions ($\langle \text{scoring-expr} \rangle$; see subsection 1.4 (Scoring)), where in most cases, the scoring expressions are either a preference counting operation or a number literal.

$\langle \text{terminal} \rangle ::= \#$ The terminal condition is specified by a conjunction, disjunction, negation, or comparison (see below).
 | $(\text{and } \langle \text{terminal} \rangle^+)$
 | $(\text{or } \langle \text{terminal} \rangle^+)$
 | $(\text{not } \langle \text{terminal} \rangle)$
 | $\langle \text{terminal-comp} \rangle$

$\langle \text{terminal-comp} \rangle ::= (\langle \text{comp-op} \rangle \langle \text{scoring-expr} \rangle \langle \text{scoring-expr} \rangle) \#$ A comparison operator is used to compare two scoring expressions (see next section).

$\langle \text{comp-op} \rangle ::= \langle | \langle = | = | \rangle | \rangle =$

For the full specification of the $\langle \text{scoring-expr} \rangle$ element, see subsection 1.4 (Scoring) below.

1.4 Scoring

Scoring rules specify how to count preferences (count once, once for each unique objects that fulfill the preference, each time a preference is satisfied, etc.), and the arithmetic to combine preference counts to a final score in the game.

The $\langle \text{scoring} \rangle$ tag is defined by the maximization or minimization of a particular scoring expression, defined by the $\langle \text{scoring-expr} \rangle$ rule. A $\langle \text{scoring-expr} \rangle$ can be defined by arithmetic operations on other scoring expressions, references to the total time or total score (for instance, to provide a bonus if a certain score is reached), comparisons between scoring expressions ($\langle \text{scoring-comp} \rangle$), or by preference evaluation rules. Various preference evaluation modes can expand the $\langle \text{preference-eval} \rangle$ rule, see the full list and descriptions below.

$\langle \text{scoring} \rangle ::= \langle \text{scoring-expr} \rangle \#$ The scoring conditions maximize a scoring expression.

$\langle \text{scoring-expr} \rangle ::= \#$ A scoring expression can be an arithmetic operation over other scoring expressions, a reference to the total time or score, a comparison, or a preference scoring evaluation.

| $\langle \text{scoring-external-maximize} \rangle$
 | $\langle \text{scoring-external-minimize} \rangle$
 | $(\langle \text{multi-op} \rangle \langle \text{scoring-expr} \rangle^+) \#$ Either addition or multiplication.
 | $(\langle \text{binary-op} \rangle \langle \text{scoring-expr} \rangle \langle \text{scoring-expr} \rangle) \#$ Either division or subtraction.
 | $(- \langle \text{scoring-expr} \rangle)$
 | (total-time)

- | (total-score)
- | $\langle \text{scoring-comp} \rangle$
- | $\langle \text{preference-eval} \rangle$

$\langle \text{scoring-external-maximize} \rangle ::= (\text{external-forall-maximize } \langle \text{scoring-expr} \rangle) \#$ For any preferences under this expression inside a (forall ...), score only for the single externally-quantified object that maximizes this scoring expression.

$\langle \text{scoring-external-minimize} \rangle ::= (\text{external-forall-minimize } \langle \text{scoring-expr} \rangle) \#$ For any preferences under this expression inside a (forall ...), score only for the single externally-quantified object that minimizes this scoring expression.

$\langle \text{scoring-comp} \rangle ::= \#$ A scoring comparison: either comparing two expressions, or checking that two ore more expressions are equal.

- | $(\langle \text{comp-op} \rangle \langle \text{scoring-expr} \rangle \langle \text{scoring-expr} \rangle)$
- | $(= \langle \text{scoring-expr} \rangle^+)$

$\langle \text{preference-eval} \rangle ::= \#$ A preference evaluation applies one of the scoring operators (see below) to a particular preference referenced by name (with optional types).

- | $\langle \text{count-nonoverlapping} \rangle$
- | $\langle \text{count-overlapping} \rangle$
- | $\langle \text{count-once} \rangle$
- | $\langle \text{count-once-per-objects} \rangle$
- | $\langle \text{count-nonoverlapping-measure} \rangle$
- | $\langle \text{count-unique-positions} \rangle$
- | $\langle \text{count-same-positions} \rangle$
- | $\langle \text{count-maximal-nonoverlapping} \rangle$
- | $\langle \text{count-maximal-overlapping} \rangle$
- | $\langle \text{count-maximal-once-per-objects} \rangle$
- | $\langle \text{count-maximal-once} \rangle$
- | $\langle \text{count-once-per-external-objects} \rangle$

$\langle \text{count-nonoverlapping} \rangle ::= (\text{count-nonoverlapping } \langle \text{pref-name-and-types} \rangle) \#$ Count how many times the preference is satisfied by non-overlapping sequences of states.

$\langle \text{count-overlapping} \rangle ::= (\text{count-overlapping } \langle \text{pref-name-and-types} \rangle) \#$ Count how many times the preference is satisfied by overlapping sequences of states.

$\langle \text{count-once} \rangle ::= (\text{count-once } \langle \text{pref-name-and-types} \rangle) \#$ Count whether or not this preference was satisfied at all.

$\langle \text{count-once-per-objects} \rangle ::= (\text{count-once-per-objects } \langle \text{pref-name-and-types} \rangle) \#$ Count once for each unique combination of objects quantified in the preference that satisfy it.

$\langle \text{count-nonoverlapping-measure} \rangle ::= (\text{count-nonoverlapping-measure } \langle \text{pref-name-and-types} \rangle) \#$ Can only be used in preferences including a $\langle \text{once-measure} \rangle$ modal, maps each preference satisfisfaction to the value of the function evaluation in the $\langle \text{once-measure} \rangle$.

$\langle \text{count-unique-positions} \rangle ::= (\text{count-unique-positions } \langle \text{pref-name-and-types} \rangle) \#$ Count how many times the preference was satisfied with quantified objects that remain stationary within each preference satisfcation, and have different positions between different satisfactions.

$\langle \text{count-same-positions} \rangle ::= (\text{count-same-positions } \langle \text{pref-name-and-types} \rangle) \#$ Count how many times the preference was satisfied with quantified objects that remain stationary within each preference satisfcation, and have (approximately) the same position between different satisfactions.

$\langle \text{count-once-per-external-objects} \rangle ::= (\text{count-once-per-external-objects } \langle \text{pref-name-and-types} \rangle) \#$ Similarly to count-once-per-objects, but counting only for each unique object or combination of objects quantified in the (forall ...) block including this preference.

$\langle \text{pref-name-and-types} \rangle ::= \langle \text{name} \rangle \langle \text{pref-object-type} \rangle^* \#$ The optional $\langle \text{pref-object-type} \rangle$ s are used to specify a particular instance of the preference for a given object, see the $\langle \text{pref-forall} \rangle$ syntax above.

$\langle \text{pref-object-type} \rangle ::= : \langle \text{name} \rangle \#$ The optional type name specification for the above syntax. For example, `pref-name:dodgeball` would refer to the preference where the first quantified object is a dodgeball.

2 Non-Grammar Definitions

2.1 Predicates

The predicates are not defined as part of the grammar, but rather, we envision them as being specific to a domain and being specified to any model as part of the model inputs. Predicates can act on any number of arguments, and return a Boolean value.

The following enumerates all predicates currently found in our game dataset:

```
(above <arg1> <arg2>) [5 references] ; Is the first object above the second object?
(adjacent <arg1> <arg2>) [76 references] ; Are the two objects adjacent? [will probably be
    implemented as distance below some threshold]
(adjacent_side <3 or 4 arguments>) [14 references] ; Are the two objects adjacent on the sides
    specified? Specifying a side for the second object is optional, allowing to specify <obj1> <
    side1> <obj2> or <obj1> <side1> <obj2> <side2>
(agent_crouches ) [2 references] ; Is the agent crouching?
(agent_holds <arg1> <arg2>) [327 references] ; Is the agent holding the object?
(between <arg1> <arg2> <arg3>) [7 references] ; Is the second object between the first object
    and the third object?
(broken <arg1> <arg2>) [2 references] ; Is the object broken?
(equal_x_position <arg1> <arg2>) [2 references] ; Are these two objects (approximately) in the
    same x position? (in our environment, x, z are spatial coordinates, y is the height)
(equal_z_position <arg1> <arg2>) [5 references] ; Are these two objects (approximately) in the
    same z position? (in our environment, x, z are spatial coordinates, y is the height)
(faces <arg1> <arg2>) [6 references] ; Is the front of the first object facing the front of the
    second object?
(game_over ) [4 references] ; Is this the last state of gameplay?
(game_start ) [3 references] ; Is this the first state of gameplay?
(in <arg1> <arg2>) [121 references] ; Is the second argument inside the first argument? [a
    containment check of some sort, for balls in bins, for example]
(in_motion <arg1> <arg2>) [311 references] ; Is the object in motion?
(is_setup_object <arg1> <arg2>) [10 references] ; Is this the object of the same type
    referenced in the setup?
(object_orientation <arg1> <arg2>) [15 references] ; Is the first argument, an object, in the
    orientation specified by the second argument? Used to check if an object is upright or
    upside down
(on <arg1> <arg2>) [166 references] ; Is the second object on the first one?
(open <arg1> <arg2>) [3 references] ; Is the object open? Only valid for objects that can be
    opened, such as drawers.
(opposite <arg1> <arg2>) [4 references] ; So far used only with walls, or sides of the room, to
    specify two walls opposite each other in conjunction with other predicates involving these
    walls
(rug_color_under <arg1> <arg2>) [11 references] ; Is the color of the rug under the object (
    first argument) the color specified by the second argument?
(same_color <2 or 3 arguments>) [23 references] ; If two objects, do they have the same color?
    If one is a color, does the object have that color?
(same_object <arg1> <arg2>) [7 references] ; Are these two variables bound to the same object?
(same_type <arg1> <arg2>) [5 references] ; Are these two objects of the same type? Or if one is
    a direct reference to a type, is this object of that type?
(toggled_on <arg1> <arg2>) [4 references] ; Is this object toggled on?
(touch <arg1> <arg2>) [49 references] ; Are these two objects touching?
(type <arg1> <arg2>) [9 references] ; Is the first argument, an object, an instance of the type
    specified by the second argument?
```

2.2 Functions

Functions operate similarly to predicates, but rather than returning a Boolean value, they return a numeric value or a type. Similarly to predicates, functions are not a part of the grammar, and may vary by problem domain.

The following describes all functions currently found in our game dataset:

```
(building_size ) [2 references] ; Takes in an argument of type building, and returns how many
    objects comprise the building (as an integer).
(distance ) [114 references] ; Takes in two arguments of type object, and returns the distance
    between the two objects (as a floating point number).
(distance_side ) [5 references] ; Similarly to the adjacent_side predicate, but applied to
    distance. Takes in three or four arguments, either <obj1> <side1> <obj2> or <obj1> <side1> <
    obj2> <side2>, and returns the distance between the first object on the side specified to
    the second object (optionally to its specified side).
(x_position ) [4 references] ; Takes in an argument of type object, and returns the x position
    of the object (as a floating point number).
```

2.3 Types

The types are also not defined as part of the grammar, and we envision them operating similarly to the predicates and functions, varying by domain and provided to any models as part of its inputs .

The following describes all types currently found in our game dataset:

```
game_object [2 references] ; Parent type of all objects
agent [N/A references] ; The agent
building [N/A references] ; Not a real game object, but rather, a way to refer to structures the agent builds
----- Blocks -----
block [2 references] ; Parent type of all block types:
bridge_block [5 references]
cube_block [12 references]
blue_cube_block [7 references]
tan_cube_block [N/A references]
yellow_cube_block [7 references]
flat_block [2 references]
pyramid_block [9 references]
blue_pyramid_block [2 references]
red_pyramid_block [1 reference]
triangle_block [3 references]
yellow_pyramid_block [1 reference]
cylindrical_block [8 references]
tall_cylindrical_block [5 references]
----- Balls -----
ball [2 references] ; Parent type of all ball types:
beachball [17 references]
basketball [18 references]
dodgeball [49 references]
blue_dodgeball [6 references]
red_dodgeball [N/A references]
pink_dodgeball [6 references]
golfball [23 references]
green_golfball [N/A references]
----- Colors -----
color [N/A references] ; Likewise, not a real game object, mostly used to refer to the color of the rug under an
    object
blue [1 reference]
brown [1 reference]
green [5 references]
pink [12 references]
orange [3 references]
purple [4 references]
red [8 references]
```

```

tan [1 reference]
white [1 reference]
yellow [12 references]
----- Other moveable/interactable objects -----
alarm_clock [8 references]
book [9 references]
blinds [N/A references] ; The blinds on the windows
chair [2 references]
cellphone [6 references]
cd [6 references]
credit_card [1 reference]
curved_wooden_ramp [1 reference]
desktop [4 references]
doggie_bed [9 references]

3 Modal Definitions in Linear Temporal Logic

3.1 Linear Temporal Logic definitions

We offer a mapping between the temporal sequence functions defined in subsection 1.2 (Gameplay Preferences) and linear temporal logic (LTL) operators. As we were creating this DSL, we found that the syntax of the $\langle \text{then} \rangle$ operator felt more convenient than directly writing down LTL, but we hope the mapping helps reason about how we see our temporal operators functioning. LTL offers the following operators, using φ and ψ as the symbols (in our case, predicates). Assume the following formulas operate sequence of states S_0, S_1, \dots, S_n :

- **Next**, $X\psi$: at the next timestep, ψ will be true. If we are at timestep i , then $S_{i+1} \vdash \psi$
- **Finally**, $F\psi$: at some future timestep, ψ will be true. If we are at timestep i , then $\exists j > i : S_j \vdash \psi$
- **Globally**, $G\psi$: from this timestep on, ψ will be true. If we are at timestep i , then $\forall j : j \geq i : S_j \vdash \psi$
- **Until**, $\psi U \varphi$: ψ will be true from the current timestep until a timestep at which φ is true. If we are at timestep i , then $\exists j > i : \forall k : i \leq k < j : S_k \vdash \psi$, and $S_j \vdash \varphi$.
- **Strong release**, $\psi M \varphi$: the same as until, but demanding that both ψ and φ are true simultaneously: If we are at timestep i , then $\exists j > i : \forall k : i \leq k \leq j : S_k \vdash \psi$, and $S_j \vdash \varphi$.

Aside: there's also a **weak until**, $\psi W \varphi$, which allows for the case where the second is never true, in which case the first must hold for the rest of the sequence. Formally, if we are at timestep i , if $\exists j > i : \forall k : i \leq k < j : S_k \vdash \psi$, and $S_j \vdash \varphi$, and otherwise, $\forall k \geq i : S_k \vdash \psi$. Similarly there's **release**, which is the similar variant of strong release. We're leaving those two as an aside since we don't know we'll need them.

3.2 Satisfying a $\langle \text{then} \rangle$ operator

Formally, to satisfy a preference using a $\langle \text{then} \rangle$ operator, we're looking to find a sub-sequence of S_0, S_1, \dots, S_n that satisfies the formula we translate to. We translate a $\langle \text{then} \rangle$ operator by translating the constituent sequence-functions ($\langle \text{once} \rangle$, $\langle \text{hold} \rangle$, $\langle \text{while-hold} \rangle$)¹ to LTL. Since the translation of each individual sequence function leaves the last operand empty, we append a 'true' (\top) as the final operand, since we don't care what happens in the state after the sequence is complete.

(once ψ) := $\psi X \dots$

(hold ψ) := $\psi U \dots$

(hold-while $\psi \alpha \beta \dots \nu$) := $(\psi M \alpha) X (\psi M \beta) X \dots X (\psi M \nu) X \psi U \dots$ where the last $\psi U \dots$ allows for additional states satisfying ψ until the next modal is satisfied.

For example, a sequence such as the following, which signifies a throw attempt:

```
(then
  (once (agent_holds ?b))
  (hold (and (not (agent_holds ?b)) (in_motion ?b)))
  (once (not (in_motion ?b)))
)
```

Can be translated to LTL using $\psi := (\text{agent_holds ?b})$, $\varphi := (\text{in_motion ?b})$ as:

$\psi X (\neg \psi \wedge \varphi) U (\neg \varphi) X \top$

Here's another example:

```
(then
  (once (agent_holds ?b))       $\alpha$ 
  (hold-while
    (and (not (agent_holds ?b)) (in_motion ?b))   $\beta$ 
    (touch ?b ?r)   $\gamma$ 
  )
  (once (and (in ?h ?b) (not (in_motion ?b))))   $\delta$ 
)
```

If we translate each predicate to the letter appearing in blue at the end of the line, this translates to:

$\alpha X (\beta M \gamma) X \beta U \delta X \top$

¹These are the ones we've used so far in the interactive experiment dataset, even if we previously defined other ones, too.
